Case Study: A Full AI-Assisted Shift

Dominic Yeakel

9/17/2026

Morning Triage

The analyst leaned on AI to work through routine alerts more efficiently, but checked every suggested verdict before marking it resolved. As a result, the queue cleared at a noticeably faster pace than a comparable shift the week prior.

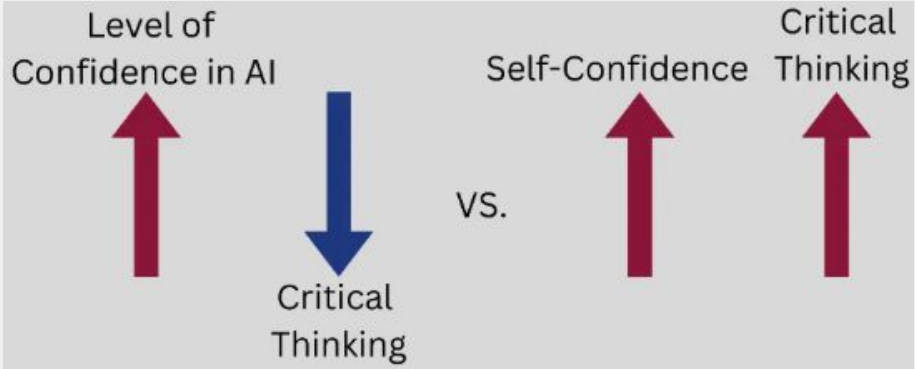

The analyst let AI move through routine alerts without checking each proposed verdict before closing it out. The queue cleared quickly, but a few closures were based on assumptions the analyst never confirmed, and no one would know until something slipped through.

Midday Incident

Once an incident was verified, the analyst asked AI to draft a concise summary and a stakeholder-facing update, then sharpened each one with a targeted follow-up prompt. Both documents were finished with time to spare before the notification deadline.

When the incident was confirmed, the analyst took the AI-drafted summary and stakeholder update and sent them out as-is, without refining either for accuracy or context. Both went out ahead of the notification window, but the update lacked details a manual reviewer would have caught.

The Result

The shift wrapped up with thorough documentation and nothing overlooked with AI helping move things along, but every judgment call remained the analyst's own. That balance is exactly what today's skill set is designed to achieve.

The shift closed with tickets marked resolved and notes filed, but the analyst couldn't fully explain how several verdicts were reached. AI carried the workload, and judgment took a back seat. This is the opposite of what today's skills are meant to produce.
