Case Study: Data Analytics Informing a Policy Change

Aggregated data at Meridian Trust Bank revealed something no single incident had made obvious.

Dominic Yeakel | 9/25/2026

1 The Pattern

The Pattern

Analysts noticed that a disproportionate share of confirmed fraud cases involved a specific type of account change request. No individual case had stood out enough to trigger this realization on its own.

REAL-WORLD PARALLEL *Global AP fraud case, apexanalytix client (multi-country)*

- A global organization found fraudsters were compromising supplier email accounts specifically to request bank account changes on outgoing payments.
- One attempt tried to redirect a $1.4 million payment this way
- It only read as a pattern once similar attempts started stacking up across multiple countries and suppliers.

2 The Analysis

The Analysis

Aggregated fraud trend data confirmed the pattern was statistically significant and growing over the prior six months. This is exactly the kind of trend individual investigations are not designed to surface.

REAL-WORLD PARALLEL *Global AP fraud case, apexanalytix client (multi-country)*

- Manual, case-by-case email verification couldn't keep pace. In the organization's own words, “the old, manual controls just weren't working anymore.”
- Centralizing bank-change requests through one system was what finally made the trend visible across six countries: the US, UK, Sweden, Poland, India, and Czech Republic.
- As with our case study, the fix wasn't smarter individual reviewers, it was aggregating the data so the trend could be seen at all.

3 The Outcome

The Outcome

The bank added a new verification step specifically for that type of request, directly reducing losses in the following quarter. This is analytics driving a concrete, measurable security improvement.

REAL-WORLD PARALLEL *Global AP fraud case, apexanalytix client (multi-country)*

- The organization rolled out automated bank account ownership validation (legal entity matching, account status, and account age) for every change request.
- That single control blocked a follow-up $14 million fraud attempt outright, plus four more after it.
- Since implementation, zero payment fraud incidents

THE LESSON

No single case revealed the pattern. The aggregate data did.

Analysts spotted it. Analytics confirmed it. Policy fixed it. This is what data-driven security looks like.
